Edup Ed 1540 Wireless Driver v8.1.0.4 (13.05.03).Neuroprotection by indomethacin and its analogues in two rat models of Parkinson's disease. Parkinson's disease (PD) is a neurodegenerative disease that can be treated by the enzyme tyrosine hydroxylase (TH). The neuroprotective effects of indomethacin and its analogues may occur by a TH-dependant pathway. Therefore, the aim of this study was to evaluate neuroprotection using indomethacin and its analogues in both in vivo and in vitro models of PD. Indomethacin and analogues 1-[[4-[[3-(trifluoromethyl)-phenylimino]methyl]phenyl]methyl]amino]ethyl]-benzene-sulfonate (P), N-(2,6-dimethylphenyl)-N'-(4-fluorophenyl)urea (U), and N-(2,4,6-trimethylphenyl)-N'-(4-fluorophenyl)urea (T) were studied in the 6-hydroxydopamine (6-OHDA) model of PD. A TH-inhibitor, (1S)-(αR)-(+)-4-amino-4-carboxy-N-phenyl-1-butanol (raclopride) was used to test the hypothesis that the neuroprotective effect of indomethacin is TH-dependant. The mice were injected in the medial forebrain bundle (MFB) with 6-OHDA (2 μL of 1 μg/μL) and treated with a 1-week injection of indomethacin (10 mg/kg), P, U, or T, with or without a chronic injection of (raclopride) (1 mg/kg) for 7 days. The mice treated with indomethacin, P, U, and T exhibited a significant increase in TH protein expression compared with 6-OHDA treated mice. The indomethacin analogues
