But the PDF of the Gamma distribution is a shifted version of the PDF of the exponential distribution. There are two questions: 1) Why does the Gamma distribution have this relationship with the exponential distribution? 2) Why is it not possible to determine if a non-integer number of observations is being sampled from a Gamma distribution with just the shape parameter? A: To answer the first question, let's first look at the relation between the two distributions. The density of the $\text{Gamma}(\alpha, \beta)$ distribution is $f_{\text{Gamma}}(y | \alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} y^{\alpha-1} e^{-\beta y}$, $y \geq 0$
