Software fingerprint solution X100cComprehensive evaluation of protein quality and digestibility of Cicer arietinum L. processed with thiram. The potential use of legumes as an alternative to meat in the human diet requires the in-depth evaluation of their nutritional value. Thiram has been reported as a legume bio-antagonist, possibly affecting the growth and development of several seeds. However, no information is available regarding the role of this fungicide on the nutritional quality of raw legumes. In this study, the effect of thiram on the nutritional quality of Cicer arietinum L. beans during the soaking, cooking and germination stage was studied by adopting the rabbit feeding test and the Trypsin Digestibility Test. Results were compared with those of untreated beans and values of the same parameters of a standard legume, soybean. Thiram, used as a soil fungicide, slightly inhibited both growth and metabolism at doses of 0.02 and 0.1 kg kg-1 fresh weight. Significant losses of all nutrients studied were registered after cooking and during the germination stage, while higher losses were registered during the soaking stage. Thiram also inhibited the trypsin activity, and this effect negatively affected the digestion process, affecting the protein and starch digestibility index. The nutritional value of thiram-treated beans was similar to that of untreated ones, even though the digestibility index was markedly reduced. These results indicate that thiram as a soil fungicide seems to be harmless as long as its concentration does not exceed 0.02 kg kg-1 fresh weight.While it may seem like a very convenient time to take a financial risk, those who have managed their own finances in the past will most likely tell you that there are times when it is best not to take a leap of faith.
