It is well known that impurities can be separated from aqueous media by placing the impurities on bubbles of gas that are detached from the bulk of the medium. For example, in the case of a pulp and paper mill, some of the impurities of the pulp can be floated and carried off to a different part of the mill by the bubbles of air that the pulp creates in the process. However, it is equally well known that these bubbles of air can be captured and removed, for instance by periodically flushing the paper machine, to prevent excessive foaming in the process. One method of producing impurity-containing foam that can be separated from the aqueous media is to subject the aqueous medium to the action of ultrasound in the presence of a foamifying gas. The application of ultrasound is believed to cause nucleation and growth of bubbles of gas, in a phenomenon called cavitation, to produce foam. By subjecting the aqueous medium to cavitation in the presence of bubbles of gas
