Escherichia coli O157:H7 is one of the most important bacterial pathogens in the USA and other countries. A major determinant of the virulence of E. coli O157:H7 is the production of the outer membrane protein (Omps) as also the enterohaemorrhagic (EHEC) variant of these bacteria. The EHEC-O157 L-OmpT protein is tightly regulated post-translationally with each of the two paralogues differentially expressed in response to different growth conditions. While the Omps are among the most highly expressed proteins, they are also the most labile making them useful as vaccine antigens. While there are a number of approaches to vaccination, the majority of research is focused on serum antibody and there is a need for alternative methods. One of these approaches is DNA vaccination where plasmids encoding Omps are delivered into a cell. This project will examine one of the most critical post-translational regulation of L-OmpT, namely, the ability of the bacteria to sense the length of L-OmpT. Regulation is achieved through L-OmpT being either over-produced or not at all with both OmpT paralogues being made at different levels and in different combinations. The

The PIVOT Statement is a data transformation technique that takes advantage of the way a SQL Server database engine retrieves data from its tables. SQL Server does not provide native support for the PIVOT statement in the SELECT and/or ORDER BY clause. However, it can be implemented in a variety of ways. The following explains and provides examples of the four best known methods, with some performance considerations to help you decide the best method for your implementation of the pivot. Method #1: Create a Clustered Indexed View If the source of your query is a view, you can create a clustered index for the view. This allows the view to use the clustered index as an effective sort key for the data in the query. You can build the clustered index for the view based on the columns of the view without breaking any assumptions of your database schema. For example, if the view has columns that you want to order by, but don't want to sort in that order in the view, you can assign the view the ascending sort order instead. The following creates a clustered indexed view for a query that returns the names and
