How does AutoCAD work? In AutoCAD, users work directly in 2D views of their drawing. In 3D work, users create blocks, geometries, symbols and surfaces. Each AutoCAD object has its own properties, named attributes. The attributes are used in many functions of the drawing, such as moving and copying objects, deleting objects, setting color, etc. The fundamental idea is that each attribute has a value, and a name. You can use a mouse to drag and drop objects, move them, edit them, and define their attributes. You can also use the keyboard to move, copy, and delete objects, edit their attributes and use menus to select objects. In AutoCAD, you create objects in layers. Each object has its own assigned layer and a separate area, or region. Layers are arranged to mimic a schematic representation of a drawing. For example, your drawing might have a “structure” layer, a “detail” layer and a “interior” layer, as well as the separate drawing area. Each layer has a separate set of layer properties and a separate color and linetype that is applied to all objects on that layer. Each layer is used to control which objects are visible and which are hidden. The visibility of objects is controlled by changing the object’s layer and region properties. You can change the visibility of objects using layers. In AutoCAD, you can apply a color and linetype to a layer. In other words, AutoCAD has the concept of a layer property. A linetype is a property that is applied to the objects on a layer. AutoCAD also has a line style property that you can use to apply a line style to a layer. In AutoCAD, the “line style” is often referred to as a “line type” and a “line property.” The ability to edit objects is closely related to the layer system. You can select an object using a layer (or region) property, and change its properties. Layer properties can also be used to hide or show objects. The fundamental idea of AutoCAD is that each object has its own layer and properties. The “layer property” is the attribute that is applied to the layer. The “object property” is the attribute that is applied to the object. One of the

Medroxyprogesterone acetate (MPA) was used for metastatic breast cancer with high risk of recurrence. It is one of the most widely used progestin for chemotherapy of breast cancer. MPA is a potent androgen, which might have a potential risk of tumor growth in breast and soft tissue. In this paper, we discuss the clinical features and the management of breast mass after high dose MPA in patients with metastatic breast cancer. Twenty-eight patients with metastatic breast cancer were treated with medroxyprogesterone acetate. Among them, eight patients developed breast mass after administration of high dose MPA. We retrospectively reviewed their clinical features. Of eight patients, seven patients underwent surgical removal of the breast mass after treatment of high dose MPA, because of growth of the mass or suspicion of malignancy. All of the patients had received high dose MPA at the time of the breast mass development. The breast mass was palpable in all of the eight patients. In some cases, the breast mass was noticed first and, after 4 weeks, patients felt the breast mass as a mass. The breast mass was soft in six patients, but hard in the other two. The breast mass was single in six patients, but multiple in two. The median duration of MPA administration was 8 weeks. The median interval between the discontinuation of MPA and the surgical removal of the breast mass was 33 weeks. The
