In a packet-based network, such as an Ethernet network, the computing devices communicate data by dividing the data into small blocks called packets, which are individually routed across the network from a source device to a destination device. A variety of intermediate devices operate to route the packets between the computing devices. For example, a computer network may include routers, switches, gateways, firewalls, and a variety of other devices to facilitate the communication of the packets. Virtual private networks (VPNs) may provide secure communication for users of the VPN. In VPNs, access to various resources of a network is controlled based on a secure, encrypted communication channel. Various data security and identity authentication services may also be provided by the VPN. In an example, a VPN may allow a corporate user to access a corporate intranet or file server without exposing the user to an open internet. The VPN provides this secure access by encrypting the communications between the user's computing device and the intranet or file server. Thus, communications between the computing device and the intranet are secure, as they are encrypted using cryptographic algorithms. In an example, a VPN uses security protocols to bind a tunnel to a single packet flow. The tunnel is established by 3e33713323
